Solution Manual: Assembly Language Programming and Organization of the IBM PC by Ytha Yu Charles Marut

Question 1: Explain the concept of an interrupt.

Answer: An interrupt is a hardware or software event that causes a processor to temporarily halt its current execution and switch to a special routine to handle the

event. Interrupts are used to respond to external events, such as keyboard input or device failures, and to execute privileged instructions.

Question 2: How does the 8088 microprocessor address memory?

Answer: The 8088 microprocessor uses a 20-bit address bus, allowing it to address up to 1 MB of physical memory. Memory is organized into 16-bit segments, and each segment is up to 64 KB in size.

Question 3: Describe the difference between a procedure and a macro.

Answer: A procedure is a sequence of instructions that can be called from multiple locations within a program. A macro is a definition that expands into a sequence of instructions at the point where it is used. Procedures allow for code reuse and modularity, while macros simply simplify the writing of repetitive code patterns.

Question 4: How does the DOS interrupt service handle input and output operations?

Answer: The DOS interrupt service provides a set of interrupt handlers that can be called by programs to perform input and output operations. These handlers handle tasks such as printing to the console, reading from the keyboard, and opening and closing files.

Question 5: Explain the use of the stack in assembly language programming.

Answer: The stack is a data structure used to store temporary data and control flow information during program execution. In assembly language, the stack is used for arguments to procedures, local variables, and return addresses. The top of the stack is always pointed to by the stack pointer register.
