Question and Answer on Solution of Digital Signal Processing by Proakis (3rd Edition)

Q1: Explain the concept of the discrete-time Fourier transform (DTFT). A1: The DTFT represents a continuous-time signal as a series of complex exponentials with discrete frequencies. It describes the frequency response of a signal and enables frequency-domain analysis.

Q2: Describe the operation of a digital filter. A2: Digital filters are mathematical algorithms that process digital signals to remove unwanted noise or enhance desired features. They are designed using transfer functions and can be implemented as finite impulse response (FIR) or infinite impulse response (IIR) filters.

Q3: Explain the difference between causal and non-causal systems. A3: Causal systems only depend on present and past inputs, while non-causal systems depend on future inputs as well. Causality is an important consideration in signal processing as it affects the stability and latency of digital systems.

Q4: Discuss the role of windowing in spectral analysis. A4: Windowing is a technique used to limit the leakage caused by the truncation of the DTFT. It involves multiplying the signal by a window function, which smoothes the edges of the signal and reduces spectral artifacts.

Q5: Explain the concept of the fast Fourier transform (FFT) algorithm. A5: The FFT is a computationally efficient algorithm that performs the DTFT of a large sequence of data. It reduces the computational complexity by exploiting the periodicity of the DTFT. The FFT is widely used in spectral analysis, image processing, and other applications.
