The Cell: A Molecular Approach by Geoffrey M. Cooper

1. What is the central dogma of molecular biology?

The central dogma states that genetic information flows unidirectionally from DNA to RNA to protein. DNA is transcribed into RNA, which is then translated into protein. This process is essential for cells to synthesize the proteins they need to function.

2. How is the genetic code translated?

The genetic code is translated by ribosomes, which are large molecular machines that reside in the cytoplasm. Ribosomes bind to mRNA molecules and read the sequence of codons (three-nucleotide sequences). Each codon corresponds to a specific amino acid, and the ribosome links the amino acids together in the correct order to form a protein.

3. What is the role of enzymes in cellular metabolism?

Enzymes are proteins that catalyze chemical reactions in cells. They speed up the rate of reactions by lowering the activation energy required for the reaction to occur. Enzymes are essential for a wide range of cellular processes, including metabolism, digestion, and DNA replication.

4. How do cells regulate gene expression?

Cells regulate gene expression through a variety of mechanisms, including transcriptional regulation, translational regulation, and epigenetic modifications. Transcriptional regulation involves controlling the initiation of transcription, while translational regulation involves controlling the translation of mRNA into protein. Epigenetic modifications are changes to the DNA that do not alter the sequence but affect gene expression.

5. What are the different types of cell death?

Cell death is an essential process for maintaining tissue homeostasis and eliminating damaged or unwanted cells. There are two main types of cell death: apoptosis and necrosis. Apoptosis is a programmed form of cell death that occurs in response to internal signals, while necrosis is an uncontrolled form of cell death that occurs in response to external injuries.
