[Download Complete File](#)

What's true about watersheds? Healthy watersheds are vital for a healthy environment and economy. Our watersheds provide water for drinking, irrigation and industry. Many people also enjoy lakes and streams for their beauty and for boating, fishing and swimming. Wildlife also need healthy watersheds for food and shelter.

What is a water flowing downslope along Earth's surface along a definite path? Streams and Drainage Systems. A stream is a body of water that carries rock particles and dissolved ions and flows down slope along a clearly defined path, called a channel. Thus, streams may vary in width from a few centimeters to several tens of kilometers.

How does the speed of surface water movement relate to the size of soil particles the moving water can carry? Water Speed and Erosion Faster-moving water has more kinetic energy. Therefore, it can carry larger particles.

Does humus create soil spaces which increase the soil's ability to hold water? Soil also affects its water-holding capacity. Soil consists of decayed organic matter, called humus, and minerals. Humus creates pores in the soil, thereby increasing a soil's ability to retain water. The minerals in soil have different particle sizes, which are classified as sand, silt, or clay.

What is a watershed answer key? A watershed is an area of land that channels rainfall, snowmelt, and runoff into a common body of water.

Are watersheds good or bad? We all live in a watershed, and watershed condition is important to everyone and everything that uses and needs water. Healthy

watersheds provide critical services, such as clean drinking water, productive fisheries, and outdoor recreation, that support our economies, environment and quality of life.

What is the movement of water along the earth's surface called? The water cycle, also known as the hydrologic cycle, describes where water is stored on Earth and how it moves. Water is stored in the atmosphere, on the land surface, and below the ground.

What is an example of a surface runoff? Surface runoff occurs whenever the soil is saturated with water and cannot absorb any more moisture, such as during a flash flood or rapid snow melt. Surface runoff also occurs when water settles on impervious surfaces, such as concrete driveways and asphalt covered roads, before flowing into storm sewers.

What is a moving body of surface water that flows downslope? 1. A stream is a body of water that flows down-slope within a restricted passageway (channel) while transporting detrital particles and dissolved substances. 2. The sediment and dissolved matter transported by the stream is called its load.

What are the two main factors that control stream erosion and sediment transport? Several factors cause streams to erode and transport sediment, but the two main factors are stream channel gradient and velocity. The stream gradient is the slope of the river channel. A steeper gradient promotes downward stream erosion.

What are the factors affecting erosion and deposition? Agents of erosion include water, wind, glaciers, and gravity. Factors that affect the rate of erosion include weather, climate, shape of the land, and type of rock. The presence of plants and the way humans use the land affect the rate of erosion. The rate of erosion sometimes depends on the type of rock.

What is an excessive amount of water flowing downslope along Earth's surface called? An Excessive amount of water flowin downslope along earths surface is called. Runoff. A streams systems, or drainage basin, is all of the land area whose water drains into a stream system.

How is humus formed? In addition to the plant material in leaf litter, humus is composed of decaying animals, such as insects, and other organisms, such as mushrooms. Humus is dark, organic material that forms in soil when plant and animal matter decays. When plants drop leaves, twigs, and other material to the ground, it piles up.

What are two ways that humus improves soil conditions for plant growth? Humus improves soil fertility by acting as a reservoir for nutrients, increasing the water holding capacity of the soil, improving soil structure and friability, and providing a source of energy for living soil organisms.

How does soil water holding capacity affect plant growth? Too much water can also be a problem, leading to standing water, erosion, and nutrient loss. A soil with a low water holding capacity will have a narrow window between too much and not enough moisture. Both conditions lead to poor plant growth.

Which of the following is true about a watershed? The statement that is true is: Watersheds can be any size or shape. A watershed refers to an area of land where all water drains to a single body of water such as a river, lake, or ocean. It includes all the land, hills, and mountains surrounding a body of water that drains into it.

What are three facts about watersheds? A watershed is the land area that drains to a common body of water, such as a stream, lake, bay, or even the ocean. They provide drinking water, habitats for wildlife, soil to grow our food, and locations for fishing, boating and swimming. We all live in a watershed.

What are 5 things that watersheds provide? Healthy watersheds provide many ecosystem services including, but not limited to: nutrient cycling, carbon storage, erosion/sedimentation control, increased biodiversity, soil formation, wildlife movement corridors, water storage, water filtration, flood control, food, timber and recreation, as well as reduced ...

What are three characteristics of a watershed? Structural features such as faults and fractures can also influence the drainage pattern. Each watershed is unique. Characteristics include, but are not limited to, the total area of the watershed, its shape, the arrangement of slopes and the overall relief or elevation change.
