Q1: What is the structure of DNA? A: DNA is a double helix composed of two strands of nucleotides. Each nucleotide consists of a deoxyribose sugar, a phosphate group, and a nitrogenous base (adenine, thymine, guanine, or cytosine). The two strands are held together by hydrogen bonds between the bases, with adenine pairing with thymine and guanine pairing with cytosine.

Q2: How is genetic information encoded in DNA? A: Genetic information is encoded in the sequence of nucleotides in DNA. The order of the bases determines the amino acid sequence of proteins, which in turn determines the phenotype of an organism.

Q3: What is the role of RNA in protein synthesis? A: RNA plays a crucial role in protein synthesis by carrying genetic information from DNA to the ribosomes, where proteins are assembled. There are three main types of RNA: messenger RNA (mRNA), transfer RNA (tRNA), and ribosomal RNA (rRNA). mRNA carries the genetic code from DNA, tRNA brings amino acids to the ribosomes, and rRNA forms the structural components of ribosomes.

Q4: What is transcription? A: Transcription is the process by which the genetic information in DNA is copied into RNA. It is carried out by RNA polymerase, which recognizes specific sequences in DNA called promoters. RNA polymerase synthesizes a complementary RNA molecule that carries the same genetic information as the DNA template.

Q5: What is translation? A: Translation is the process by which the genetic information in RNA is converted into a protein. It occurs on ribosomes, which read the RNA molecule and assemble amino acids into a polypeptide chain. The amino acid sequence of the polypeptide chain is determined by the sequence of nucleotides in the RNA molecule.
