Which statement best describes the theory of plate tectonics multiple choice question? Answer: The statement that best describes the theory of plate tectonics is the one that says that sections of Earth's continents are in slow constant movement.

What forms where two tectonic plates slide past each other multiple choice question? At transform boundaries, tectonic plates are not moving directly toward or directly away from each other. Instead, two tectonic plates move past each other in a horizontal direction. This kind of boundary results in a fault. A fault is a crack or fracture in the earth's crust that is associated with this movement.

What does the theory of plate tectonics state _____? The theory of plate tectonics states that the Earth's outermost layer (lithosphere) is fragmented into large and small plates. These plates are moving relative to one another as they lie on hotter, more mobile material (asthenosphere).

What does the theory of plate tectonics describe _____? The theory of plate tectonics describes movement of plates of the Earth's crust through time.

What are the 4 types of plate boundaries? There's four main types you'll need to know. These are constructive, destructive, collision and conservative - these basically are just different ways that two tectonic plates could interact. Constructive (also known as divergent) is the two plates pulling apart away from each other (or diverging).

When two continental plates pull apart, a _____ forms? When two continental plates diverge, a valleylike rift develops. This rift is a dropped zone where the plates are pulling apart. As the crust widens and thins, valleys form in and around the area, as do volcanoes, which may become increasingly active.

What are the three types of plate boundaries when two plates move? Most seismic activity occurs at three types of plate boundaries—divergent, convergent, and transform. As the plates move past each other, they sometimes get caught and

pressure builds up.

What is the theory of plate tectonics answers? Plate tectonics is the theory that states that Earth's outer shell is divided into several plates that glide over the mantle. The plates act like a hard and rigid shell compared to Earth's mantle. This strong outer layer is called the lithosphere. Plate tectonics is the modern version of continental drift.

What causes the plate to move? The plates can be thought of like pieces of a cracked shell that rest on the hot, molten rock of Earth's mantle and fit snugly against one another. The heat from radioactive processes within the planet's interior causes the plates to move, sometimes toward and sometimes away from each other.

What are the two of Earth's largest plates? The largest plates are the Antarctic, Eurasian, and North American plates. Plates are on average 125km thick, reaching maximum thickness below mountain ranges. Oceanic plates (50-100km) are thinner than the continental plates (up to 200km) and even thinner at the ocean ridges where the temperatures are higher.

Which type of crust is usually the oldest? Continental crust is almost always much older than oceanic crust. Because continental crust is rarely destroyed and recycled in the process of subduction, some sections of continental crust are nearly as old as Earth itself.

What is the plastic-like layer of the mantle called? The Upper Mantle, also known as the asthenosphere, bends like plastic. The layer can bend as this layer is made up of soft rocks. The rocks bend due to the high temperatures from the core that partially heats the asthenosphere and make it soft.

How does sea floor spreading occur? Seafloor Spreading is the usual process at work at divergent plate boundaries, leading to the creation of new ocean floor. As two tectonic plates slowly separate, molten material rises up from within the mantle to fill the opening.

What is the name of the famous transform fault in California, USA? The San Andreas Fault is the transform plate boundary where a thin sliver of western California, as part of the Pacific Plate, slides north-northwestward past the rest of

North America.

What happens to the earth's crust in a collision zone? Collision Zones and Mountains Instead, a collision between two continental plates crunches and folds the rock at the boundary, lifting it up and leading to the formation of mountains and mountain ranges. Select each label for additional information. The earth's crust that makes up the continents.

Is transform constructive or destructive? destructive boundaries (convergent): where plates are moving towards each other and old crust is either dragged down into the mantle at a subduction zone or pushed upwards to form mountain ranges. transform boundaries (conservative): where plates are moving past each other and crust is neither created nor destroyed.

What land formation is produced by the convergence of two oceanic plates? Island Arcs An island arc is a series of islands formed at a convergent boundary. Island arcs mostly form from oceanic-oceanic boundaries or oceanic-continental boundaries where subduction occurs. As the denser plate is subducted, magma flows to the surface and creates new landmasses in the island arc.

What natural disaster occurs often near this type of boundary? Final answer: Earthquakes often occur at the boundaries between tectonic plates due to the movement and interaction of the plates.

What is the stress called when the plates come together? Compressive stress happens at convergent plate boundaries where two plates move toward each other. Tensional stress happens at divergent plate boundaries where two plates are moving away from each other.

What is a famous transform boundary? Transform faults are not limited to oceanic crust and spreading centers; many of them are on continental margins. The best example is the San Andreas Fault on the Pacific coast of the United States.

What is it called when one plate slides underneath another? This process, called “subduction,” involves an older, denser tectonic plate being forced deep into the planet underneath a younger, less-dense tectonic plate.

What do the plate names refer to? Scientists have identified 7 major tectonic plates. In order from largest to smallest, they are the Pacific Plate, the North American Plate, the Eurasian Plate, the African Plate, the Antarctic Plate, the Indo-Australian Plate, and the South American Plate. Each plate is named based on what lies above it.

Which statement best explains the theory of plate tectonics? Expert-Verified Answer The statement that best explains the theory of plate tectonics is as follows: Earth's crust is composed of rock plates that float on top of the mantle (option B).

Which of the following best describes the plate tectonic theory? Answer. Answer: Plate tectonics is the theory that Earth's outer shell is divided into several plates that glide over the mantle, the rocky inner layer above the core. The plates act like a hard and rigid shell compared to Earth's mantle.

Which statement properly describes the plate tectonics theory? Answer. Answer: Earth's crust is divided into moving pieces that collide with each other, creating mountain ranges, ocean ridges, and ocean trenches.

Which of these is best explained by the theory of plate tectonics? The theory of plate tectonics revolutionized the earth sciences by explaining how the movement of geologic plates causes mountain building, volcanoes, and earthquakes.

What is the theory of plate tectonics answers? Plate tectonics is the theory that states that Earth's outer shell is divided into several plates that glide over the mantle. The plates act like a hard and rigid shell compared to Earth's mantle. This strong outer layer is called the lithosphere. Plate tectonics is the modern version of continental drift.

What is best explained by plate tectonics quizlet? Plate tectonics explains the connection between continental drift and the formation and destruction of crust along plate boundaries. It also helps to explain the occurrence of earthquakes, volcanoes, and mountains.

What is the theory of plate tectonics ____ *? According to the theory of plate tectonics, large pieces of Earth's lithosphere, called plates, move slowly over Earth's surface driven by convection currents in the mantle. Plates can include oceanic

and/or continental lithosphere.

Which of the following best describes plate tectonics? Explanation: The Theory of Plate Tectonics describes the movement of Earth's lithospheric plates. Option B, 'All of Earth's plates are moving in a slow and constant motion,' is the best description of the Theory of Plate Tectonics.

What are the three causes of plate movement? Convection in the Mantle (heat driven) Ridge push (gravitational force at the spreading ridges) Slab pull (gravitational force in subduction zones)

What are the three types of plate boundaries? There are three kinds of plate tectonic boundaries: divergent, convergent, and transform plate boundaries. This image shows the three main types of plate boundaries: divergent, convergent, and transform. Image courtesy of the U.S. Geological Survey.

Which statement correctly describes plate tectonics? AI-generated answer. The statement that accurately describes plate tectonics is "The lithosphere is broken into sections called plates." Plate tectonics refer to the theory that the lithosphere is broken into a number of sections or plates that move and interact with one another.

Which statement about the theory of plate tectonics is correct? Explanation: According to plate tectonics theory, the Earth's lithosphere is divided into several large plates that move and interact with each other. The statement that is true according to plate tectonics theory is that these plates are in constant motion.

Which explanation best describes this plate tectonic movement? Geologists have hypothesized that the movement of tectonic plates is related to convection currents in the earth's mantle. Convection currents describe the rising, spread, and sinking of gas, liquid, or molten material caused by the application of heat.

What best describes the plate tectonics theory? Answer. Explanation: Plate tectonics is the theory that Earth's outer shell is divided into several plates that glide over the mantle, the rocky inner layer above the core. The plates act like a hard and rigid shell compared to Earth's mantle.

How do scientists know where plate boundaries are? A plate is a rigid slab of the lithosphere moving as a unit and may be composed of ocean floor, be entirely

continental, or it may contain both oceanic and continental crust (Figure 6). Plate boundaries are defined and identified by mapping narrow belts of earthquakes, volcanoes, and young mountain ranges (Figure 7).

What are the methods used to measure plate movement? Geodesy, the science of measuring the Earth's shape and positions on it, allows the measurement of plate motion directly using GPS, the Global Positioning System. This network of satellites is more stable than the Earth's surface, so when a whole continent moves somewhere at a few centimeters per year, GPS can tell.
