Questions and Answers from Sedra/Smith 6th Edition

1. Explain the difference between an intrinsic and extrinsic semiconductor.

Answer: An intrinsic semiconductor is a pure semiconductor material with no impurities added. It has a small number of free carriers (electrons and holes) created by thermal excitation. An extrinsic semiconductor is a semiconductor material that has been doped with impurities to increase its conductivity. The impurities introduce additional free carriers, either electrons (n-type) or holes (p-type).

2. What is the depletion region in a PN junction diode?

Answer: The depletion region is the region around the PN junction where both electrons and holes have been depleted. This creates a region of high electric field that prevents further diffusion of charge carriers across the junction.

3. Describe the operation of a MOSFET.

Answer: A MOSFET (Metal-Oxide-Semiconductor Field-Effect Transistor) is a voltage-controlled switch. It consists of a source terminal, a drain terminal, a gate terminal, and a body terminal. By applying a voltage to the gate, the channel between the source and drain can be turned on or off, allowing current to flow or not flow, respectively.

4. What is the purpose of a feedback amplifier?

Answer: A feedback amplifier uses feedback from the output to the input to control the overall gain and frequency response of the amplifier. Negative feedback reduces the gain and improves stability, while positive feedback increases the gain and can lead to oscillations.

5. Explain the difference between an operational amplifier (op-amp) and a comparator.

Answer: An op-amp is a high-gain amplifier with two inputs and one output. It is designed to perform mathematical operations such as addition, subtraction, and integration. A comparator is a special type of op-amp that compares two input voltages and outputs a digital signal indicating which voltage is larger.
