The Nature and Properties of Soils: 15th Edition

What is Soil?

Soil is a complex material that covers the Earth's surface, forming the basis for terrestrial life. It consists of a mixture of mineral particles, organic matter, water, and air. The mineral particles, derived from the weathering of rocks, include sand, silt, and clay. Organic matter originates from the decomposition of plants and animals.

Soil Properties

Soils exhibit a wide range of properties that affect their suitability for plant growth and other uses. These properties include:

- **Texture:** The relative proportions of sand, silt, and clay particles.
- **Structure:** The arrangement of soil particles into aggregates or clumps.
- **Water-holding capacity:** The ability of soil to retain water for plant use.
- **pH:** A measure of soil acidity or alkalinity.
- **Organic matter content:** The amount of organic matter in the soil, which influences soil fertility.

Soil Formation

Soil formation is a complex process that occurs over time and involves the interaction of climate, organisms, topography, parent material, and time. Climate

influences the rate of weathering and decomposition, while organisms contribute to the formation of organic matter. Topography affects drainage and erosion, and parent material determines the initial composition of the soil.

Factors Affecting Soil Fertility

Soil fertility refers to the ability of soil to support plant growth. Several factors influence soil fertility, including:

- **Nutrient availability:** The presence of essential plant nutrients such as nitrogen, phosphorus, and potassium.
- **Soil pH:** pH affects the availability of nutrients and microbial activity.
- **Organic matter content:** Organic matter provides nutrients and improves water retention.
- **Soil structure:** A good soil structure allows for optimal root growth and water infiltration.
