Solution Manual PDF: Cochrane Computers Asset Pricing

Question 1: Explain the CAPM model and its assumptions.

Answer: The Capital Asset Pricing Model (CAPM) assumes that investors diversify their portfolios and seek to maximize expected returns while minimizing risk. The model states that the expected return of an asset is a linear function of its beta, which measures the asset's systematic risk relative to the market.

Question 2: What are the empirical evidence supporting and against the CAPM model?

Answer: Empirical evidence generally supports the CAPM model, indicating a positive relationship between beta and expected return. However, some studies have found that the model underestimates expected returns for high-risk assets and overestimates returns for low-risk assets.

Question 3: Describe the Fama-French three-factor model and how it extends the CAPM model.

Answer: The Fama-French three-factor model extends the CAPM model by adding two additional factors: size and value. The model suggests that smaller companies and value stocks tend to have higher expected returns than predicted by the CAPM model alone.

Question 4: What is the Arbitrage Pricing Theory (APT) and how does it differ from the CAPM model?

Answer: The APT assumes that asset returns are driven by multiple factors, rather than just beta. It does not require a representative investor or the assumption that investors are risk-averse.

Question 5: Discuss the practical applications of asset pricing models.

Answer: Asset pricing models are used to value securities, estimate the cost of capital, and make portfolio management decisions. They provide insights into the relationship between risk and return, helping investors make informed investment decisions.
