**What is surface charge of biomaterials?** The surface charge depends on chemical compositions, topography, micropatterning, stiffness of surface or material and surface free energy itself including its polar and dispersive constituents.

**What is the interaction between cells and biomaterials?** Cell-biomaterial interactions are mediated by the type and conformation of the adsorbed proteins that can interact with specific integrins expressed by the cells. These phenomena can be strongly influenced by adsorption of water molecules, a process that is dependent on the surface composition of the biomaterial.

**What determines surface charge?** The surface charge can have either a negative or positive electrical state, which is determined by the balance between negatively charged and positively charged nanoparticles at the surface.

**What are the surface modification techniques of biomaterials?** The surface modification techniques include film and coating synthesis, covalent grafting, self-assembled monolayers (SAMs), plasma surface modification and other strategies.

**How does biomaterial relate to biological material?** Biological materials are materials that are produced by living organisms, such as, blood, bone, proteins, muscle, and other organic material. Biomaterials, on the other hand, are materials which are created specifically to be used for biological applications.

**What are the four main ways that biomaterials can interact with your body?**

**Is one of the most important aspects of biomaterial tissue interactions?** Biocompatibility reflects the nature and degree of interaction between biomaterials and host tissue and is one of the critical concerns in biomaterials research (12,13,34). Biocompatibility can be defined as the ability of a material to perform with an appropriate host response in a specific application (14–17,21,33).

**What is surface property of biomaterial?** The surface properties of biomaterials are mainly described by chemistry, surface charge, texture (roughness), wettability,

and in case of polymers also by crystallinity. All these factors influence the sequence of protein adsorption and subsequent platelet adhesion/thrombus formation and attachment of cells.

**What is surface adsorption of biomaterials?** Adsorption of proteins at a biomaterial's surface generally occurs in an irreversible manner because of the much faster adsorption rate compared with the desorption rate. As a general rule, a hydrophobic character of the surface will lead to a higher tendency for protein adsorption than a hydrophilic surface.

**What is the charge of the surface of a bacteria?** At neutral pH, the majority of bacterial cells have a net negative charge as a result of the existence of peptidoglycan, which is abundant in carboxyl and amino groups. Teichoic acids with phosphate-rich constituents also contribute to the negative charge on bacterial cell walls.

**What is surface charge of nanoparticles?** Surface charge of NPs is crucial to their cellular uptake, biodistribution, and interaction with other biological environments. Generally, positively charged NPs can be more readily internalized into cells than neutrally and negatively charged NPs, due to the negatively charged nature of cell membrane [45].
