

# Arterial blood gas interpretation for the acem fellowship exam 25 worked exam

## [Download Complete File](#)

### How to interpret arterial blood gas results?

**How do you sample for arterial blood gas analysis?** For an arterial blood gas test, a respiratory therapist will take a sample of blood from one of your arteries. This is because there are higher oxygen levels in blood from an artery than blood from a vein. A respiratory therapist usually takes the sample from an artery inside your wrist known as the radial artery.

**What is the normal range for arterial blood gases?** An acceptable normal range of ABG values of ABG components is the following,[27][28] noting that the range of normal values may vary among laboratories and in different age groups from neonates to geriatrics: pH (7.35-7.45) PaO<sub>2</sub> (75-100 mm Hg) PaCO<sub>2</sub> (35-45 mm Hg)

**What is a normal arterial blood gas value in kPa?** Normal Results Values at sea level: Partial pressure of oxygen (PaO<sub>2</sub>): 75 to 100 millimeters of mercury (mm Hg), or 10.5 to 13.5 kilopascal (kPa) Partial pressure of carbon dioxide (PaCO<sub>2</sub>): 38 to 42 mm Hg (5.1 to 5.6 kPa) Arterial blood pH: 7.38 to 7.42.

**What is arterial blood gas analysis summary?** An arterial blood gas (ABG) test measures the amount of oxygen and carbon dioxide in your blood. It also checks the acidity of your blood. This is called your acid-base balance or your pH level.

**How to know if compensated or uncompensated?** It is FULLY COMPENSATED if pH is normal. It is PARTIALLY COMPENSATED if all three (3) values are abnormal. It is UNCOMPENSATED if PaCO<sub>2</sub> or HCO<sub>3</sub> is normal and the other is

abnormal.

**How do you write arterial blood gas?** ABG shorthand is often written with the numbers in that order with backslashes between them (pH/pCO<sub>2</sub>/pO<sub>2</sub>/HCO<sub>3</sub>). Don't let this confuse you. Just remember the order and you will look like a pro!

**What are the 6 steps to ABG analysis?**

**What is the correct blood sampling for blood gas analysis?** Steps for blood collection for BGA Take a little amount of heparin in a 2ml syringe to lubricate the inner wall of the syringe and then flush out the heparin completely. Collect 2ml arterial/venous blood in this heparinised syringe (filling the syringe completely is very important).

**Which arterial blood gas value is most important?** Oxygen (O<sub>2</sub>) and carbon dioxide (CO<sub>2</sub>) are the most important respiratory gases, and their partial pressures in arterial blood reflect the overall adequacy of gas exchange.

**What does an arterial blood gases test reveal?** An arterial blood gases (ABG) test measures the acidity (pH) and the levels of oxygen and carbon dioxide in the blood from an artery. This test is used to find out how well your lungs are able to move oxygen into the blood and remove carbon dioxide from the blood.

**What is the ABG for respiratory failure?** Arterial blood gas (ABG) is the gold standard for diagnosing respiratory failure. At a minimum, the information obtained from an ABG includes pH, partial pressure of arterial oxygen (PaO<sub>2</sub>), partial pressure of arterial carbon dioxide (PaCO<sub>2</sub>), and serum bicarbonate (HCO<sub>3</sub>).

**How do you interpret ABG results?**

**What is an example of a metabolic acidosis?** One such example is lactic acidosis, which is where decreased oxygen delivery to the tissues leads to increased anaerobic metabolism and the buildup of lactic acid.

**How do you interpret base excess?** Base excess (BE) A value outside of the normal range (-2 to +2 mEq/L) suggests a metabolic cause for the acidosis or alkalosis. A base excess more than +2 mEq/L indicates a metabolic alkalosis. A base excess less than -2 mEq/L indicates a metabolic acidosis.

**What do the arterial blood gas values suggest?** An arterial blood gas analysis (ABG) measures the balance of oxygen and carbon dioxide in your blood to see how well your lungs are working. It also measures the acid-base balance in the blood. Your kidneys and lungs work to keep your acid-base levels in balance.

**What if pCO<sub>2</sub> and HCO<sub>3</sub> are both high?** If pH is normal but closer to the acidotic end, and both PaCO<sub>2</sub> and HCO<sub>3</sub> are elevated, the kidneys have compensated for a respiratory problem. If the pH is normal, but closer to the alkalotic end of the normal range, and both PaCO<sub>2</sub> and HCO<sub>3</sub> are elevated, the lungs have compensated for a metabolic problem (see Table 3).

**What does low HCO<sub>3</sub> indicate?** Metabolic acidosis is a clinical disturbance defined by a pH less than 7.35 and a low HCO<sub>3</sub> level. The anion gap helps determine the cause of the metabolic acidosis. An elevated anion gap metabolic acidosis can be caused by salicylate toxicity, diabetic ketoacidosis, and uremia (MUDPILES).

**How to interpret PaO<sub>2</sub> in ABG?** The expected PaO<sub>2</sub> when breathing air at sea level can be calculated with the equation  $\text{PaO}_2 = 100 - (\text{age} \times 0.25)$ . Consequently, a PaO<sub>2</sub> of 75 mmHg, which may be of concern in a young person, is usually unremarkable in an 85-year-old. A PaO<sub>2</sub> that is less than expected indicates hypoxaemia.
