Simulated ABO Blood Typing Lab Activity Answers

Question 1: What is the purpose of blood typing? Answer: Blood typing determines the presence or absence of specific antigens on the surface of red blood cells, which helps ensure compatibility during blood transfusions and organ transplants.

Question 2: What are the different ABO blood types? Answer: There are four ABO blood types: A, B, AB, and O. Type A has antigen A, Type B has antigen B, Type AB has both A and B antigens, and Type O has neither A nor B antigens.

Question 3: How does simulated blood typing work? Answer: In simulated blood typing, synthetic blood samples with known antigens are tested with antisera containing antibodies against specific antigens. If an antigen-antibody reaction occurs, it indicates the presence of that antigen on the red blood cells.

Question 4: Why is it important to match blood types during transfusions? Answer: If a person receives a transfusion with incompatible blood, the antisera in their plasma will attack and destroy the transfused red blood cells, leading to a transfusion reaction. Matching blood types helps prevent this life-threatening event.

Question 5: What is the universal donor and universal recipient? Answer: Type O blood is the universal donor because it lacks both A and B antigens, making it compatible with all other blood types. Type AB blood is the universal recipient because it has both A and B antigens, allowing it to receive any blood type without an adverse reaction.
