What is the relationship between power factor and magnetizing current? What is the relation between the magnetizing current and power factor? Explanation: Magnetizing current is indirectly proportional to the power factor. As the magnetizing current is large, the power factor is poor.

What is the relationship between harmonics and power factor? The power factor (PF) takes into account both the effects of harmonics and cosine phi. Thus, these two negative effects are evaluated in one value: The shift of the current relative to the voltage (cosine phi) The distortion of the current compared to a perfect sine wave (THD)

What is the formula for magnetizing current? This is the magnetizing current (no secondary current) and is governed by the differential equation $V(t) = L \times d(I)/dt + R_p \times I(t)$, with units of volts, henries, amps, and seconds.

What is magnetizing current also known as? A. of transformer, that current flow in primary is called magnetizing current. Another name is exciting current, whereas creates magnetic field in core and provides energy for no-load power losses in core.

How is power factor related to current? Power Factor (PF) is the ratio of working power, measured in kilowatts (kW), to apparent power, measured in kilovolt amperes (kVA). Apparent power, also known as demand, measures the amount of power used to run machinery and equipment during a certain period. It is found by multiplying voltage (V) by current (A).

What happens to current when power factor increases? In an electric power system, a load with a low power factor draws more current than a load with a high power factor for the same amount of useful power transferred. The larger currents increase the energy lost in the distribution system and require larger wires and other equipment.
