**How to know which locus has the longest DNA fragments?** Which locus has the longest DNA fragments? CSF1PO. How do you know? Examining the size of the alleles by comparing the location of the peaks in the electropherogram to the known number of nucleotides in the DNA ladder shows that CSF1PO has the longest

fragments: about 326 bp and 330 bp.

**How do you determine whether an individual is heterozygous or homozygous for a particular STR?** If the inherited alleles for a given STR in an individual are identical (i.e., contain the same number of repeat units), the individual is homozygous for that STR. If the individual has inherited two different alleles for a given STR, then he or she is heterozygous for that STR.

**When reading an STR profile, how will the pattern of peaks appear if a person is homozygous at a locus?** In general, a homozygous locus will show a single peak that is approximately twice the height of alleles seen at a heterozygous locus within the same dye color. This is due to the doubling of the signal from two alleles of the same size.

**What does the number next under each peak represent on an STR profile?** The top number in the small box under each peak is the number of repeats. A partial repeat would be a number with a decimal. The bottom number is the peak area.

**Which DNA fragments should go the farthest?** The DNA fragments that are shortest will travel farthest, while the longest fragments will remain closest to the origin.

**How do you tell who has the smallest fragment of DNA?** Determining the smallest fragment is qualitative, not quantitative. The smallest fragment will always be the fragment closest to the bottom of the gel, regardless of that fragment's true size in base pairs. And so, no, you do not need a ladder to make this determination.

**What does the FBI use for DNA profiling?** Booking Station Rapid DNA and Combined DNA Index System (CODIS) The Rapid DNA initiative enrolls a qualified arrestee's DNA profile in CODIS?/NDIS during the booking process. The arrestee is searched against all unsolved crimes within 24 hours. NDIS is the national level of the CODIS system.

**How much DNA is needed for STR profiling?** DNA Extraction and Analysis To perform a forensic DNA analysis, DNA is first extracted from a sample. Just one nanogram of DNA is usually a sufficient quantity to provide good data. The region containing each STR is then PCR amplified and resolved according to size, giving an

overall profile of STR sizes (alleles).

**How many loci should be compared to determine a match in DNA?** There is a chance that two persons might have DNA patterns (i.e., genetic types) that match at the small number of sites examined. Nonetheless, even with today's technology, which uses 3-5 loci, a match between two DNA patterns can be considered strong evidence that the two samples came from the same source.

**How accurate is str profiling?** Thus STR analysis provides an excellent identification tool. The more STR regions that are tested in an individual the more discriminating the test becomes. However, given 10 STR loci, it can result in a genotyping error margin of 30%, or nearly one third (1/3) of the time.

**How likely is it that any two people will have the same DNA profile?** Scientists have determined that, in general, when DNA profiles consist of the alleles present at these locations the probability that two unrelated individuals will have the same DNA profile purely by chance is less than 1 in 200 billion.

**Why are short tandem repeats important?** Short tandem repeats (STRs) are short tandemly repeated DNA sequences that involve a repetitive unit of 1–6 bp. Because of their polymorphisms and high mutation rates, STRs are widely used in biological research.

**What does STR mean in DNA profiling?** Short Tandem Repeats (STR) Later in the 1990s, short tandem repeat (STR) testing appeared in forensic DNA analysis. In keeping with the name, STRs are VNTR-like regions that have very short sequences, ranging approximately 2 to 6 base pairs (bp).

**What is a pull up in DNA?** Pull-up, sometimes referred to as bleed-through, represents a failure of the analysis software to discriminate between the different dye colors used during the generation of the data. Oversaturated data can also cause the dyes to "bleed" over or pullup into another color.

**What do STR numbers mean?** The number below each STR marker indicates the number of times a particular sequence of alleles repeats itself in a specific location on the Y chromosome. The value of testing Y-DNA STR markers comes from creating a Y-DNA signature (haplotype) with them and comparing that Y-DNA

signature to others in a database.

**What cuts up DNA into tiny fragments?** Isolated DNA is first cut into readily separable fragments with restriction nucleases.

**Which DNA fragments move slower?** A current is passed through a gel, and since DNA is negatively charged, it moves towards a positive electrode. Smaller fragments travel through the gel, which is usually made from agarose or acrylamide, more quickly, whereas larger fragments move more slowly due to their size.

**Which pieces of DNA travel the fastest?** It is important to note that different forms of DNA move through the gel at different rates. Supercoiled plasmid DNA, because of its compact conformation, moves through the gel fastest, followed by a linear DNA fragment of the same size, with the open circular form traveling the slowest.

**How do you read a DNA fragmentation test?** A fragmentation percentage of 15 or less means your sperm DNA is in good condition. On the other hand, 15-25% means your sperm DNA is somewhat fragmented, and beyond 40%, fragmentation is a cause of concern.

**How do you know if your DNA is fragmented?** Spontaneous or accidental DNA fragmentation is fragmentation that gradually accumulates in a cell. It can be measured by e.g. the Comet assay or by the TUNEL assay. Its main units of measurement is the DNA Fragmentation Index (DFI). A DFI of 20% or more significantly reduces the success rates after ICSI.

**How do you predict DNA fragment size?** Scientists use a technique called gel electrophoresis to determine the length of DNA fragments. In this process, unknown samples and a DNA standard are placed in wells -- small holes -- at the edge of a gel. The standard contains fragments of known sizes, measured in base pairs.

**How do you find the longest DNA fragment?** Scientists use a technique called gel electrophoresis to determine the length of DNA fragments. In this process, unknown samples and a DNA standard are placed in wells -- small holes -- at the edge of a gel. The standard contains fragments of known sizes, measured in base pairs.

**Where do you find the largest fragment of DNA?** Explanation: The largest DNA fragment band is found closest to the well in because it travels slower through the

gel during agarose gel electrophoresis. During this process, DNA fragments are loaded into a gel and an electric field is applied.

**Which lane shows the longest DNA fragment?** The further away you are from the top the smaller of a fragment you can have. Lane 2 and 4 have the largest because they have pieces closer to the top of the KB ladder. I say that you do need a KB ladder to easily compare the different sizes of samples of DNA.

**Where on a DNA fingerprint would you find the longest fragments?** The result is a series of 'bands', with each band containing DNA molecules of a particular size. The bands furthest from the start of the gel contain the smallest fragments of DNA. The bands closest to the start of the gel contain the largest DNA fragments.
